

Hyperfine coupling constant

- Hyperfine interaction usually results in splitting of lines in an ESR spectrum.
- The interaction energy between the electron spin and a magnetic nucleus is characterized by the **hyperfine coupling constant**
- *This is represented by*
 - **A** with units of energy (Joule)
 - **a** with unit of Magnetic Field (Gauss, Tesla)

Interactions of Single Proton

- $I = \frac{1}{2}, M_I = \pm \frac{1}{2}$
- At the electron there will be one of the two local fields contributed by the proton. For each value of electron spin angular momentum quantum number M_S , the nuclear spin angular momentum quantum number M_I can have the values $\pm \frac{1}{2}$ giving rise to four different energy levels. The ESR spectrum of hydrogen atom will therefore contain two peaks.

- Allowed Transitions are $\Delta M_S = \pm 1, \Delta M_I = 0$
- $E_{+1/2, +1/2} = \frac{1}{2}g\beta H + \frac{1}{4}a$
- $E_{+1/2, -1/2} = \frac{1}{2}g\beta H - \frac{1}{4}a$
- $E_{-1/2, -1/2} = -\frac{1}{2}g\beta H + \frac{1}{4}a$
- $E_{-1/2, +1/2} = -\frac{1}{2}g\beta H - \frac{1}{4}a$

Interactions of Single Proton

From the quantitative expressions for the energy levels of hydrogen atom, in a magnetic field three things are evident

- The equality of splitting of each $M_S = \pm \frac{1}{2}$ states.
- The ordering of the M_I levels is reversed in the lower set of levels as compared to the upper set.
- Transitions occur between same values of M_I .

Electron $S(\frac{1}{2})$

Nucleus $I(\frac{1}{2})$

Selection Rule
 $\Delta M_S = \pm 1; \Delta M_I = 0$

Hyperfine Coupling

$S = \frac{1}{2};$
 $I = \frac{1}{2}$
Doublet

$h\nu$

Magnetic Field

Hyperfine Interactions In Radical Having Single Set Of Equivalent Protons

- e.g.: $^1\text{CH}_2\text{OH}$ (at low pH, OH will not interact since there is rapid exchange of H)

- The spectra will comprise of three lines of the intensity ratio 1:2:1

Hyperfine splitting with a set of three equivalent protons

e.g. methyl radical ($\cdot\text{CH}_3$)

- The example of a system having $S = \frac{1}{2}$ and $I = \frac{3}{2}$ is the methyl radical in which the unpaired electron interacts with three protons.
- There will be four values of M_I corresponding to $M_S = +\frac{1}{2}$ and four values for $M_S = -\frac{1}{2}$.
- The resultant derivative spectrum will comprise of four lines with the intensity ratio 1:3:3:1.

Hyperfine splittings are additive

- Top spectrum: 1.0 G
- Middle spectrum: 149 G , 149 G , 2.5 G
- Bottom spectrum: 149 G , 149 G , 149 G

ESR Spectral analysis

$^{13}\text{CH}_3^-$

- Two quartets
- Two coupling constants
- $a_H = 2.3 \text{ mT}$
- $a_C = 4.1 \text{ mT}$

Radical containing multiple set of equivalent protons

- e.g. $\text{HO}^-\text{CH}-\text{COOH}$
- Here $a_1 = 17.13 \text{ G}$
- $a_2 = 2.56 \text{ G}$

System having three protons, two of which are equivalent

- e.g. $.\text{CH}_2\text{OH}$ at high pH
- In general if there are sets of m and n equivalent protons in a molecule, then the maximum number of lines a_1 in the spectrum will be given by the formula $(n+1)(m+1)$. For different nuclei, the general rule is $(2n+1)(2m+1)$.
- Here $a_1 = 17.4 \text{ G}$
- $a_2 = 1.15 \text{ G}$

Hyperfine Interactions In Deuterium ($S=1/2, I=1$)

- The deuterium atom is a simple example of a system with $S=1/2$ and $I=1$.
- There are now six spin states.
- By virtue of selection rules $\Delta M_S = \pm 1$ and $\Delta M_I = 0$, there are three allowed transitions
- Thus three lines corresponding to these transitions.
- These lines will be of equal intensity since there is no coincidence of states.

Hyperfine Coupling

Electron $S(1/2)$ Nucleus $I(1)$

“triplet”

| | | |
|--|--|-----------------------------|
| $E = g\beta S_z + (hA_0)S_x I_x$ | Selection Rule $\Delta M_S = \pm 1$ (electron) | $\Delta E_1 = g\beta B + a$ |
| $E = g\beta S_z + (a)S_x I_x$ | $\Delta M_I = 0$ (nuclear) | $\Delta E_2 = g\beta B$ |
| $(hA_0 \text{ (Hz)} \rightarrow a \text{ (G)} \text{ via } g\text{-factor})$ | | $\Delta E_3 = g\beta B - a$ |

Hyperfine Splittings

Allyl Radical

- Unpaired electron in non-bonding MO
- So e interacts only with 4 terminal Hs *not* central H
- But from ESR spectrum
 - $a(\text{terminal H}) = (-)$
1.39 mT
 - $a(\text{central H}) = (+)$
0.40 mT
- Enhanced unpaired spin at terminals *and* at central H

Direct ESR analysis of a radical

- Radical cannot be diatomic
- Radical must be available at a detectable concentration
 - At least metastable
 - Frozen solution to greatly decrease radical decay
 - Can greatly complicate the spectrum due to anisotropy
 - Continuous formation inside resonator
 - Enzymatic radical formation
 - Flow experiment
- Radical characterized by hyperfine analysis
